Testing

Heads Up Poker Sim

Team Tilted

12/02/2019

The frontend and backend of the software can be tested automatically by running npm test. The frontend test will verify that the web pages are rendered properly by the client. The backend test will send an object to the backend and then make sure it can read that same object from the backend.

The rest of the software will have to be tested manually. This is done by having one user create a room and another user join that room afterwards. If this is done without having the software crash, we can verify that the software is able to connect two players together.
